Host can read and write video memory and can write the contents of the VRAM bank register

VRAM bank register:
selects which 2K bank
the host is accessing,
and also selects which
font in the font ROM
is in use

BankA12 signal
determines which
memory chip is
accessed

Decode host control
signals, generate control
signals for VRAM and
bank reg; logic is in
VRAMCtrl.pld

U803
GAL22V10

Host read/write strobes
to determine whether
access is read or write

All host address lines are
used because the VRAM hardware
does its own address decoding
(to know when video memory
is being accessed by the host)

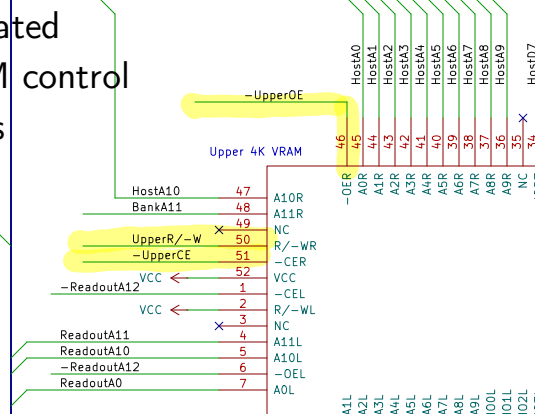

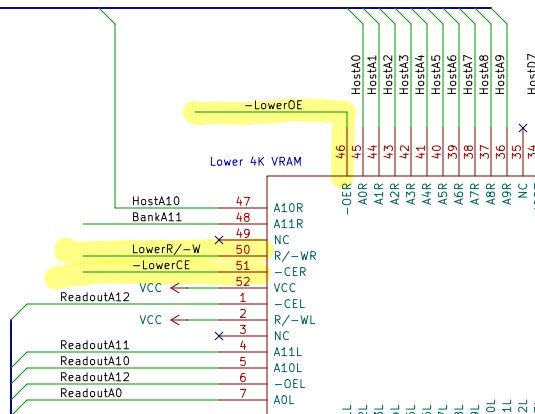

A11..A15 used
to determine when
VRAM window is
being accessed

The readout address signals
select which byte of video memory
the memory fetch hardware wants
to access. ReadoutA12 (the highest
address line) is used to select the
lower or upper VRAM chip.
