Logic is defined in
R0utCtrl.pld

U707
GAL22V10

Readout terminal count goes to
GAL since it maintains the
13th bit (ReadoutA12) of the
readout address.

Readout address register (low 12 bits,
13th bit is managed by U707)

Bank register mapped for

writing at \$80E0

Low 2 bits
select between
4 2KB VRAM
banks

HostD0
HostD1
HostD2
HostD3
HostD4
HostD5
HostD6
HostD7

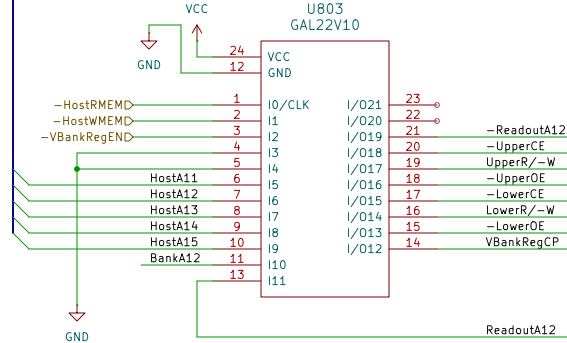

Host can read and
write video memory
and can write the
contents of the
VRAM bank register

Decode host control
signals, generate control
signals for VRAM and
bank reg; logic is in
VRAMCtrl.pld

HostA0D
HostA1D
HostA2D
HostA3D
HostA4D
HostA5D
HostA6D
HostA7D
HostA8D
HostA9D
HostA10D
HostA11D
HostA12D
HostA13D
HostA14D
HostA15D

All host address lines are
used because the VRAM hardware
does its own address decoding
(to know when video memory
is being accessed by the host)

Note that the "inversion" of
ReadoutA12 (generated by the
control signal GAL) is used to
select the high VRAM chip
and enable its output.

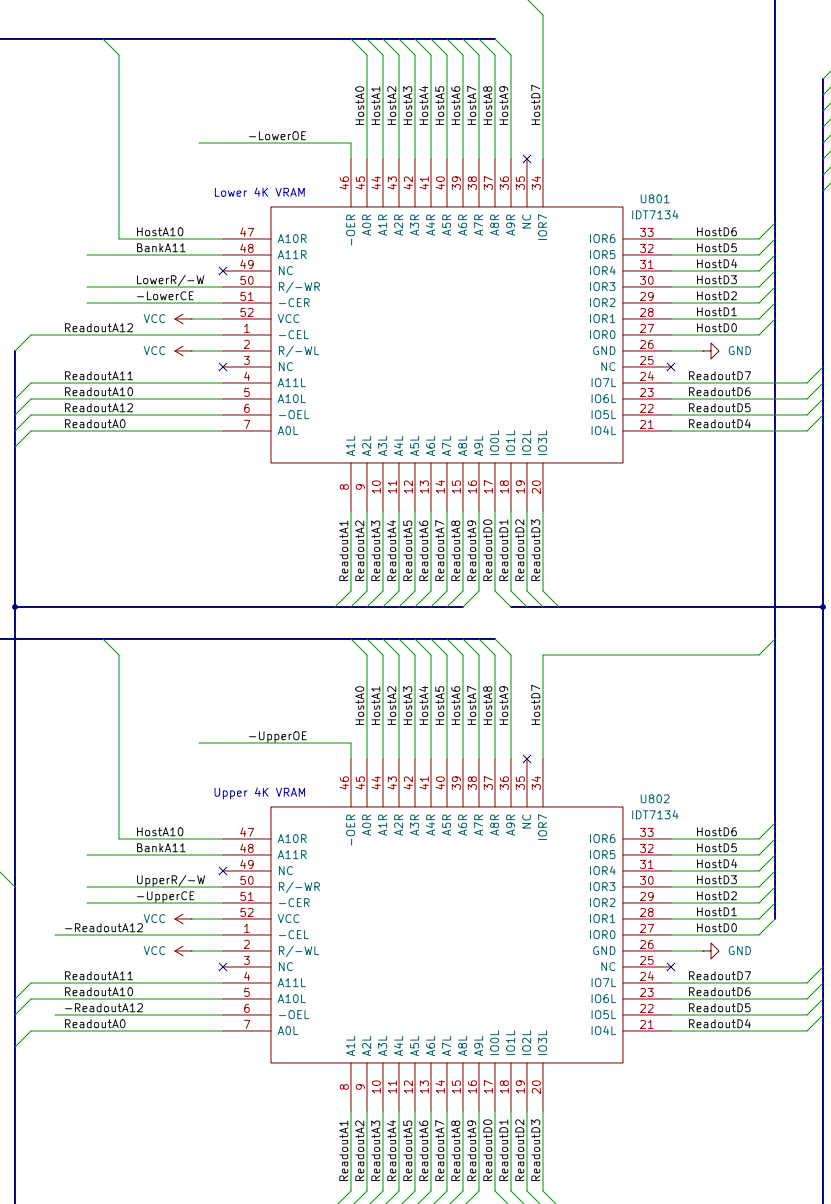

The readout address signals
select which byte of video memory
the memory fetch hardware wants
to access. ReadoutA12 (the highest
address line) is used to select the
lower or upper VRAM chip.

ReadoutA0D ReadoutA0
ReadoutA1D ReadoutA1
ReadoutA2D ReadoutA2
ReadoutA3D ReadoutA3
ReadoutA4D ReadoutA4
ReadoutA5D ReadoutA5
